Dictionary Identifier Validator Plugin

The Dictionary Identifier Validator determines if an Identifier (manually or automatically assigned) matches a Dictionary Entry.

The Dictionary Identifier Validator is available as of Registry v4.0.0.

Configuration

1. This is a non-core plugin, see Installing and Enabling Registry Plugins for more information.
2. Create the Dictionary before configuring the Plugin. The Plugin will only use the *value* of the Dictionary Entry. *code* is ignored, and *order* does not have any effect. ⚠️ Only Standard Dictionaries are supported. Do not use other Dictionary Modes.
3. The plugin Mode configures how entries in the Dictionary are used:
   a. **Contains (Case Insensitive)**: An Identifier that matches a substring of any Dictionary Entry will be rejected.
   b. **Is Exactly (Case Insensitive)**: An Identifier that exactly matches any Dictionary Entry will be rejected. Exact comparisons are more efficient, but for relatively small dictionaries (a few hundred entries) the difference should be negligible.
